Superconductivity

K. Onnes (1911) :

$$\rho \rightarrow 0 \quad \text{as} \quad T \rightarrow T_C$$

Superconductivity was discovered by Kamerlingh-Onnes in 1911 in mercury (Hg), having $T_C \approx 4 \text{ K}$

".. Mercury has passed into a new state, which on account of its extraordinary electrical properties may be called the superconductive state"

Dependence of the resistance on temperature

SUPERCONDUCTIVITY

Superconductivity is one of the most important area of solid state chemistry

Superconductors have two technologically important properties:

ZERO ELECTRICAL RESISTANCE

Superconductors carry current without energy loss

PERFECT DIAMAGNETISM

Superconductors float (levitate) above magnetic fields

$R=0$, below T_c

Perfect diamagnetism

Historic Milestones

- 1908 Making liquid helium (4.2 K)
- 1911 Discovery of zero resistance
- 1933 Meissner effect
- 1935 Londons' theory
- 1950 Ginzburg-Landau theory
- 1957 Bardeen-Cooper-Schrieffer (BCS) theory
- 1960 Magnetic flux quantization
- 1962 Josephson effect
- 1986 High-temperature superconductors

APPLICATIONS OF SUPERCONDUCTORS

The wide applicability of superconductors is due to

- Diamagnetism
- Zero resistance
- Higher current

Medical Industry

MRI Exploits the high magnetic fields expelled by superconducting wires for medical applications

Since the superconducting coils are capable of producing very stable, large magnetic field strengths, they generate high quality images.

Transportation Industry

Superconductor coils create strong magnetic fields that produce the effect of levitation by repulsion

Maglev trains hover above a magnetic field without any contact with the tracks

As a result, high speeds of up to 500 miles per hour are possible with only a small consumption of energy

Electric Power Industry

High temperature superconductors (HTS) can be used in the production of more **cost effective motors and generators**

HTS power cables can carry two to **ten times more power** in equally or smaller sized cables

FUNDAMENTAL PROPERTIES OF SUPERCONDUCTORS

Superconductors are characterized by three fundamental properties

T_c

Transitions from normal state to the superconducting state occur at a **Critical Temperature (T_c)**.

J_c

The **Critical Current Density (J_c)** is the maximum current that a superconductor can carry. Above J_c the normal state is re-installed.

H_c

A superconductor in a magnetic field, at $T < T_c$ expels the magnetic field (Meissner effect)

If the external magnetic field is increased to a critical point (H_c) it penetrates the superconductor and re-instate the normal state

The **critical magnetic field (H_c)** is the value of the applied magnetic field for which a transition from superconducting to normal state is induced

A superconducting material exhibits superconductivity only below its critical temperature T_c , its critical magnetic field H_c , and its critical current density J_c .

FUNDAMENTAL PROPERTIES OF SUPERCONDUCTORS

Superconductivity is destroyed:

- by increasing temperature at $T > T_c$
- by large magnetic field $H > H_c$

Phase diagram of a superconductor in the $H - T$ plane is described by an empirically found formula:

$$\frac{H_c(T)}{H_c(0)} = \left[1 - \left(\frac{T}{T_c} \right)^2 \right]$$

$H - T$ diagram for the superconducting state

Occurrence of Superconductivity

Occurrence:

Metallic elements, alloys, intermetallic compounds, doped semiconductors, organic metals, ...

Range of T_C :

90K for $\text{YBa}_2\text{Cu}_3\text{O}_7$.
.001K for Rh.

Si: $T_C = 8.3\text{K}$ at $P = 165 \text{ Kbar}$

Table 2 Superconductivity of selected compounds

Compound	T_c in K	Compound	T_c in K
Nb ₃ Sn	18.05	V ₃ Ga	16.5
Nb ₃ Ge	23.2	V ₃ Si	17.1
Nb ₃ Al	17.5	YBa ₂ Cu ₃ O _{6.9}	90.0
NbN	16.0	Rb ₂ CsC ₆₀	31.3
C ₆₀	19.2	MgB ₂	39.0

Occurrence of Superconductivity

Meissner Effect

Example 3: finally, a superconductor

Meissner effect:

Superconductor always
expels the magnetic flux

A superconductor in magnetic field

TYPES OF SUPERCONDUCTORS

There are two types of superconductors, Type I and Type II, according to their behaviour in a magnetic field

Type I

Type 1 superconductors show an abrupt transition from superconducting to normal state or vice-versa)

Type I superconductors are pure metals and alloys

TYPE I SUPERCONDUCTORS

Magnetization curve

$$\vec{B} = \vec{H}_0 + 4\pi\vec{M} \quad [\text{cgs}]$$

$$\vec{B} = \mu_0(\vec{H}_0 + \vec{M}) \quad [\text{SI}]$$

$\vec{B}$ magnetic induction

$\vec{H}_0$ magnetic field intensity

$\vec{M}$ magnetic moment
per unit volume

Magnetic properties can be derived from

main equations for the
superconducting state:
$$\begin{cases} \rho = 0 \\ \vec{B} = 0 \end{cases}$$

Type-I are all elements-superconductors except Nb

TYPE II SUPERCONDUCTORS

Type 2 superconductors show a gradual transition from superconducting to normal state or vice-versa

$H_{C2} \sim 41\text{T}$ for $\text{Nb}_3(\text{Al}_{0.7}\text{Ge}_{0.3})$.
 $H_{C2} \sim 54\text{T}$ for PbMo_6S_8 .

Commercial superconducting magnets of $\sim 1\text{T}$ are readily available.
